

Project Setup

To begin the development of the **DarshanEase – Temple Darshan Ticket Booking System**, the project workspace is organized into separate folders for the frontend and backend applications.

1. Create a new project folder named **DarshanEase**.
2. Inside the **DarshanEase** folder, create two subfolders:
 - **client** – Contains the React.js frontend application, including user interface components, pages, routing, and API services.
 - **server** – Contains the Node.js and Express.js backend application, including routes, controllers, models, middleware, configuration files, and database connection.
3. Open the **DarshanEase** project folder in **Visual Studio Code (VS Code)** to begin development.
4. The frontend (**client**) and backend (**server**) are developed independently while communicating through REST APIs.
5. The backend is connected to **MongoDB** for storing user, temple, booking, slot, and payment data, while the frontend provides a responsive interface for devotees and administrators.

This project structure ensures a clear separation between the client-side and server-side code, making the application easier to develop, maintain, and scale.
